Problem 1: Cyclic Substring Maximum Sum

You are given a string **S** consisting of lowercase English alphabets. Each character has a value equal to its position in the alphabet (i.e., `a = 1, b = 2, ..., z = 26`).

You are allowed to perform the following operation:

- Choose any **cyclic substring** of the string (i.e., substring can wrap from end to beginning).

Your task is to:

- Find the **maximum possible sum** of character values from any cyclic substring such that **no character appears more than once** in the chosen substring.

🔹 Input Format:

- First line: A string **S**

🔹 Output Format:

- Print a single integer representing the maximum sum.

🔹 Constraints:

- $1 \leq |S| \leq 10^5$

Example:

Input:

```
abca
```

Output:

```
6
```

🔹 Explanation:

Possible cyclic substrings:

- "abc" → sum = 1 + 2 + 3 = 6
- "bca" → sum = 2 + 3 + 1 = 6
- "cab" → sum = 3 + 1 + 2 = 6

Maximum = **6**
